Spectrum of Topics Covered in This Course

Problem Setting: Communication Over a Channel

Robert Bamler · Lecture 1, Part 1 of the course "Data Compression With and Without Deep Probabilistic Models" · Summer Term of 2023 · more course materials at https://robamler.github.io/teaching/compress23/

Goal: transmit a message from *sender* to *receiver*

- **efficiently**, i.e., using the channel as little as possible
- reliably, i.e., without errors or with as little (relevant) distortion as possible

Admin Stuff

- ▶ time and place
- ▶ resources (problem sets + solutions, lecture notes, videos, ...)
 - website: https://robamler.github.io/teaching/compress23/
 - Outdated Ilias link
 - new videos every Friday (covering lecture from preceding Wednesday)
- exam: 26 July during lecture hours (tentatively)

Preview: Source-Channel Separation Theorem

We'll prove in Lecture 10 that one can (in principle) always use a more modular setup:

Robert Bamler - Lecture 1, Part 1 of the course "Data Compression With and Without Deep Probabilistic Models" - Summer Term of 2023 - more course materials at https://robamler.github.io/teaching/compress23,

| 7

Test Your Understanding

- ▶ Question 1: Consider a data source that generates messages which are strings of *N* bits. Further, consider a channel that transmits one bit each time it is invoked, but it sometimes flips the transmitted bit due to noise. You want to communicate one message, and you want to be certain beyond reasonable doubt that the receiver can decode the message without errors. How many times do you have to invoke the channel?
 - (a) N bits (b) more than N bits (c) fewer than N bits (d) it depends
- ▶ Question 2: Consider a noise-free channel and a message with some redundancies (e.g., English text). What should an encoder and a decoder do with these redundancies?
- ▶ Question 3: Same message as in Question 2, but now with a noisy channel. What additional task do encoder and decoder have to do now? Think again about redundancies.

Outlook

- ▶ Problem 0.1 on Problem Set 0: simple examples of source coding vs. channel coding
- ► Coming up: "Lossless Compression I: Symbol Codes"
 - unique decodability & prefix codes
 - ► Huffman coding (used in zip, gzip, png, ...)

Lossless Compression I: Symbol Codes

Robert Bamler • Summer Term of 2023

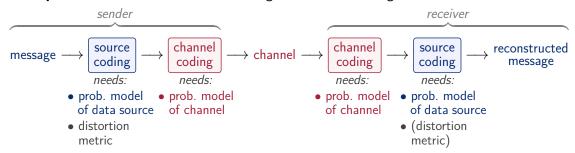

These slides are part of the course "Data Compression With and Without Deep Probabilistic Models" taught at University of Tübingen. More course materials—including video recordings, lecture notes, and problem sets with solutions—are publicly available at https://robamler.github.io/teaching/compress23/.

Overview

▶ **Recap from last video:** Source Coding & Channel Coding

- ► This course: focus on source coding, i.e., data compression
 - ▶ We'll begin with *lossless* compression.
- ► Two approaches to lossless compression:
 - (a) symbol codes: conceptionally simple but suboptimal
 - (b) **stream codes:** more involved but close to optimal

Definitions and Notation

- Running example:
 - ▶ a data source generates ASCII-encoded text of variable length;
 - \triangleright we want to send the message $\mathbf{x} =$ "Rosebud" over a noise-free binary channel.
- **▶** More generally:
 - ▶ The message **x** is a variable-length sequence of symbols from a discrete alphabet:

$$\mathbf{x} = (x_1, x_2, \dots, x_{k(\mathbf{x})}) \in \mathfrak{X}^*$$
 where

 \mathfrak{X} is called the "alphabet" (discrete set, known to sender and receiver);

 $k(\mathbf{x})$ is the length of a given message \mathbf{x} ;

 $x_i \in \mathfrak{X}$ is called a "symbol" $\forall i \in \{1, \dots, k\}$;

 $\mathfrak{X}^* := \bigcup_{k \geq 0} \mathfrak{X}^k$ is called the "Kleene closure" of \mathfrak{X} .

▶ **The channel** transmits *B*-ary bits, i.e., elements of $\{0, ..., B-1\}$ for some $B \ge 2$.

Robert Bamler · Lecture 1, Part 2 of the course "Data Compression With and Without Deep Probabilistic Models" · Summer Term of 2023 · more course materials at https://robamler.github.io/teaching/compress2:

12

Definition of Symbol Codes

- ▶ **Have:** discrete alphabet \mathfrak{X} , message $\mathbf{x} = (x_1, x_2, \dots, x_{k(\mathbf{x})}) \in \mathfrak{X}^*$, lossless B-ary channel.
- ▶ Goal (lossless compression): find a mapping $\mathfrak{X}^* \to \{0,\ldots,B-1\}^*$ such that
 - ▶ the mapping is *injective* (i.e., invertible); and
 - the resulting bit strings are short.
- ▶ B-ary symbol code: map each x_i to a bit string $C(x_i)$, then simply concatenate them.

$$\mathcal{C}:\mathfrak{X} \rightarrow \{0,\dots,B-1\}^*$$
 is called the "code book";

 $C(x_i)$ is called the "code word" for symbol $x_i \in \mathfrak{X}$;

 $|C(x_i)|$ denotes the length of the code word (i.e., the number of B-ary bits);

 $C^*(\mathbf{x}) := C(x_1) \parallel C(x_2) \parallel \ldots \parallel C(x_{k(\mathbf{x})})$ is the resulting encoding of the message \mathbf{x} ;

 $|C^*(\mathbf{x})| = \sum_{i=1}^{k(\mathbf{x})} |C(x_i)|$ denotes the length of the encoding (= "bit rate")

Examples of Symbol Codes

► Morse code

- 1. The length of a dot is one unit.
- 2. A dash is three units.
- 3. The space between parts of the same letter is one unit.
- 4. The space between letters is three units.
- The space between words is seven units.

(figure source: Wikipedia; CC-0)

Examples of Symbol Codes

- ► Morse code
- ▶ UTF-8

Code point ↔ UTF-8 conversion

First code point	Last code point	Byte 1	Byte 2	Byte 3	Byte 4	Code points
U+0000	U+007F	0xxxxxxx				128
U+0080	U+07FF	110xxxxx	10xxxxxx			1920
U+0800	U+FFFF	1110xxxx	10xxxxxx	10xxxxxx		[a]61440
U+10000	[b]U+10FFFF	11110xxx	10xxxxxx	10xxxxx	10xxxxx	1048576

15

Examples of Symbol Codes

- ► Morse code
- ▶ UTF-8
- ► Counterexample (not a symbol code): molecular formulae in chemistry

 - $\qquad \qquad \text{ethane:} \quad \begin{array}{ccc} \stackrel{H}{\underset{-}{\overset{} {\text{H}}}} & \stackrel{H}{\underset{-}{\overset{} {\text{H}}}} \\ \stackrel{-}{\underset{-}{\text{H}}} & \stackrel{-}{\underset{-}{\text{H}}} & = C_2 H_6 \\ \end{array}$
 - ▶ propane: $H C C C H = C_3H_8$
 - ▶ Note: The DEFLATE algorithm (used in zip, gzip, png, ...) works somewhat similarly.

Robert Bamler - Lecture 1, Part 2 of the course "Data Compression With and Without Deep Probabilistic Models" - Summer Term of 2023 - more course materials at https://robamler.github.io/teaching/compress2

6

Examples of Symbol Codes

- ► Morse code
- ▶ UTF-8
- ► Counterexample: molecular formulae in chemistry
- ► Toy Example: Simplified Game of Monopoly (SGoM)
 - ▶ message $\mathbf{x} \in \mathfrak{X}^*$ is sequence of symbols;
 - ▶ for each symbol: throw a pair of fair dice and record their sum;
 - for simplicity, let's use 3-sided dice $\Rightarrow \mathfrak{X} = \{2, 3, 4, 5, 6\}.$

X	$C^{(1)}(x)$	$C^{(2)}(x)$	$C^{(3)}(x)$	$C^{(4)}(x)$	$C^{(5)}(x)$	
2	10	010	010	10	010	
3	11	011	10	011	01	
4	100	100	00	11	00	
5	101	101	11	00	11	
6	110	110	011	010	110	

Properties of Symbol Codes

A symbol code with code book $C: \mathfrak{X} \to \{0, \dots, B-1\}^*$ is called

- "uniquely decodable" if the resulting code $C^*: \mathfrak{X}^* \to \{0, \dots, B-1\}^*$ is injective
 - necessary property for lossless compression
 - lacktriangle difficult to prove in general since it requires reasoning over \mathfrak{X}^*
- "prefix free" (aka, C is a "prefix code") if no code word is a prefix of another code word
 - more formally:
 - \blacktriangleright easier to prove than unique decodability since it requires only reasoning over \mathfrak{X} .
 - easier to decode than non-prefix-free codes (using a greedy algorithm).

We will show ...

- \blacktriangleright ... on Problem Set 1 that "prefix free" \Rightarrow "uniquely decodable" but not the reverse;

Optimal Symbol Codes: Huffman Codes [Huffman, 1952]

- Our first example of an *entropy coder:* $[probabilistic model p of a data source] \longmapsto [lossless compression code C]$
- **Example** for SGoM:

Robert Bamler - Lecture 1, Part 2 of the course "Data Compression With and Without Deep Probabilistic Models" - Summer Term of 2023 - more course materials at https://robaaler.github.io/teaching/compress2

| 12

Huffman Coding for B=2 (and finite \mathfrak{X})

Informal algorithm: create a binary tree whose leaves are the symbols $x \in \mathfrak{X}$ as follows:

- \blacktriangleright start from the leaves; each leaf $x \in \mathfrak{X}$ is represented as a node with weight p(x);
- while the graph is not fully connected:
 - \triangleright identify two nodes with lowest weights w and w' among all nodes that don't yet have a parent;
 - \triangleright combine these two nodes by introducing a parent node with weight w + w';
 - ▶ label the edges from the new parent node to its two children with "0" and "1" in arbitrary order;
- \blacktriangleright interpret the resulting tree as a *trie* for a prefix code on \mathfrak{X} .

More formal algorithm: Problem Set 1

Claim: Huffman codes are *optimal* uniquely decodable symbol codes (i.e., they minimize L_C).

Proof: Lecture 3

Outlook

- ▶ Problem Set 0: simple warm-up exercises (mostly SGoM)
- ▶ **Problem Set 1:** Huffman coding
 - breaking ties
 - ▶ implementation in Python
- ▶ Next 2 videos: Source Coding Theorem
 - ▶ fundamental theoretical bound for lossless compression
 - ▶ We'll prove both that a certain bound holds and that it is meaningful in practice.
- ► Later videos:
 - ▶ use machine learning to model the data source
 - even better lossless codes than Huffman codes (stream codes)
 - lossy compression
